

09 Security Misconfiguration - Part 1

Security misconfiguration occurs when applications, servers, databases, or cloud services are set up with insecure settings.

Common mistakes include failing to change default passwords, leaving unnecessary services exposed, exposing error messages, not applying security patches, and leaving storage buckets publicly accessible, giving attackers a way to access sensitive data or take control of a system.

This risk is commonly mentioned in the OWASP Top 10 and can be reduced by hardening systems, turning off unnecessary services, and running frequent software updates and audits.
