

My implementation uses a hierarchical orchestrator to coordinate agents sequentially, with an iterative Writer–Critic feedback loop. It does not use parallel execution.

My system models a coordinated investigation workflow using hierarchical control, sequential research, and iterative review. In a production system, I would secure tool access, validate inputs and outputs, protect shared state, and require authorization for consequential actions.

I will use this tool n8n tools that is like workflow to generate agent and it is not cheap and I watched few videos about n8n and it does good jobs. I also have to read book “n8n AI Automation” later on.
