

Using this module, I discovered that function calling enables a language model to function as a decision-maker rather than merely as a text generator; it reads the name, description, and JSON schema of the tool, decides upon the need for the tool, and then returns a structured call containing typed arguments, after which my own code carries out the action and feeds the result back to the model so that it can reason about it.

In cybersecurity engineering I plan to combine these ideas to achieve the automation of phishing triage; upon a user reporting a suspicious email the model should generate a structured record from the raw message and its headers (including the sender domain, the discrepancy between the reply-to and the sender, the embedded URLs, the attachment hashes, the urgent language, and a risk category chosen from a fixed Enum).
