

06 Insufficient Logging & Monitoring

The failure to log and to monitor represents a security vulnerability since security-related events are not recorded or because the logs are not watched.

Attacks would go undetected for months if login attempts, access failures, and important transactions were not properly logged, allowing the attackers to gain higher privileges and steal data.

This issue is featured in the OWASP Top 10 and is currently listed as "Security Logging and Alerting Failures".

To stop this from happening, organizations ought to make sure that key events are logged together with the appropriate context, store the logs in a central and secure place, avoid recording any sensitive data, install alerts for odd patterns, and have an incident response plan ready so that threats can be detected and dealt with swiftly.
