

05 Improper Assets Management

A lack of proper asset management results from a weakness in API security when an organization fails to properly monitor all of its API endpoints, versions, and environments.

Many old versions, forgotten development servers, and undocumented endpoints remain accessible long after they should have been deleted, since they are guarded by weaker mechanisms than the current ones.

In order to obtain sensitive data or to bypass security controls, attackers deliberately concentrate on the access points.

Risk can be reduced by keeping a full and current inventory of the API, documenting each endpoint, getting rid of the unused versions, and making sure that all environments are given the same security patches and monitoring.
